

# Getting The Crop In

*Trial results from 2014*

Sarah Noack

Research & Extension Manager, Hart Field-Site Group

# Hart – rainfall 2014

<b>Average GSR (Apr-Oct)</b>	<b>305 mm</b>	<b>Average rainfall</b>	<b>400 mm</b>
2014 GSR (Apr-Oct)	280 mm	2014 total rainfall	426 mm
2014 GSR (Apr-Oct)+summer	392 mm		

- Wheat time of sowing
- Management strategies for improved productivity and reduced nitrogen losses
- Harvest weed seed control – Narrow windrow burning in canola

# Wheat time of sowing

## Why do the trial?

- Majority of our current wheat varieties need to be sown in the first half of May to flower during the optimal period for grain yield.
- Research in southern NSW has shown they have well adapted winter and slow maturing cultivars that when sown in mid-late April will out-yield fast maturing cultivars sown in May.
- Currently options for growers in SA who wish to sow early are not well known.

# Wheat time of sowing

## Wheat varieties trialed

Exposure to cool temperatures

Variety	Maturity
EGA Wedgetail	Mid-maturing winter (strong vernalisation moderate photoperiod)
Rosella	Fast-maturing winter (strong vernalisation weak photoperiod)
Trojan	Mid-fast maturing spring (moderate vernalisation, moderate photoperiod)
Mace	Fast-maturing spring (weak vernalisation, weak photoperiod)
RAC1843	Very fast maturing spring (no vernalisation, no photoperiod)

Day length response

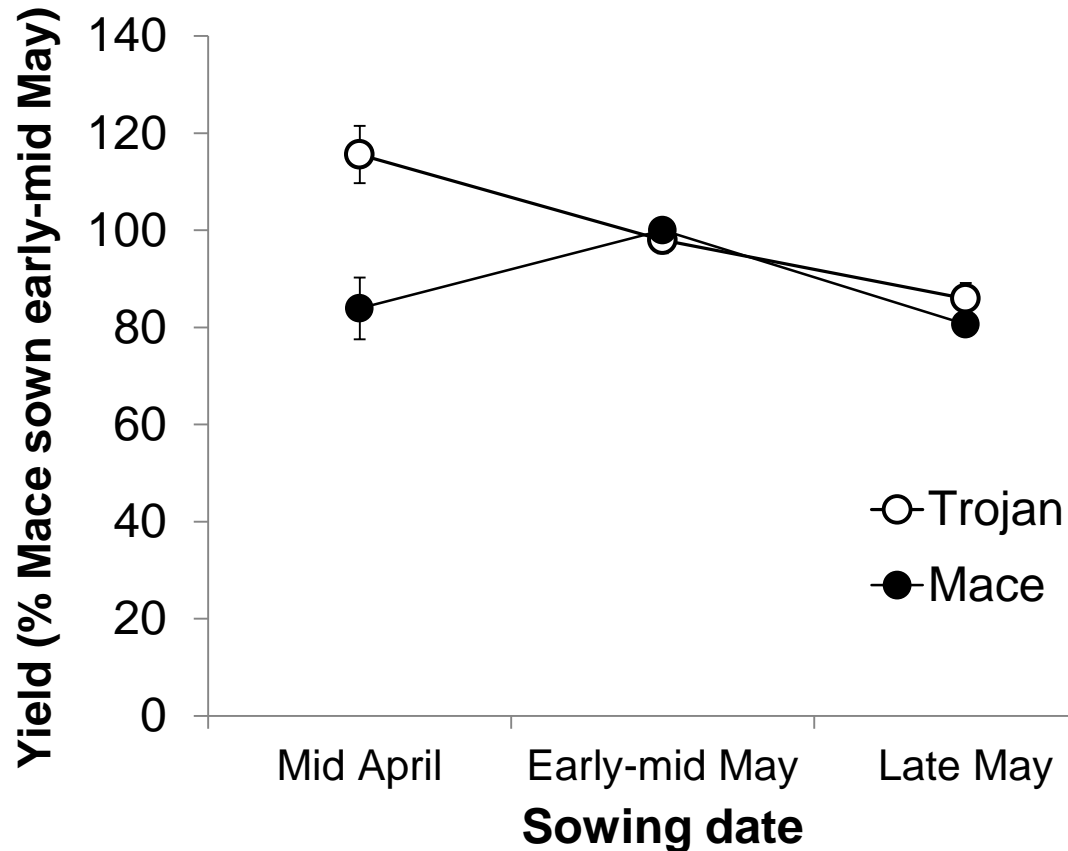

# Wheat time of sowing – grain yield

Yield (t/ha)	Time of sowing		
	Cultivar	14-Apr	8-May
Wedgetail	4.5	4.0	3.0
Rosella	4.3	3.7	2.8
Trojan	5.7	5.3	3.7
Mace	3.9*	4.7	3.3
RAC1843	0.8*	3.6	3.5
LSD (P≤0.05)		0.3	

\* frost damage

- Trojan sown on 14 April and 8 May were the highest yielding wheat treatments, out-yielding Mace sown on 8 May by 1.0 and 0.6 t/ha, respectively.
- Slow maturing cultivars bred in other states (Wedgetail and Rosella) showed poor adaptation to SA and this was also reflected at four other sites.

# Cereal time of sowing – all trial sites

- Similar result was achieved in experiments at Minnipa, Cummins, Pt Germein and Tarlee.
- Trojan can be included in cropping program to complement Mace (general rule of thumb, 7-10 days earlier than Mace from 2014 data).

# Management strategies for improved productivity and reduced nitrogen losses

## Why do the trial?

- Four nitrogen gases can be lost from soil and fertiliser applications.
- Nitrous oxide is a greenhouse gas with 300x warming potential of carbon dioxide.
- We sample nitrous oxide as it is the easiest gas to measure.
- *AIM: To measure how much soil/fertiliser nitrogen we are losing to the air during the growing season.*

## Trail design

- 1) Crop rotation
- 2) N rate and timing
- 3) Nitrification inhibitors
- 4) Tactical using Greenseeker®

2013 lentil

2014 Mace wheat

2013 canola

- 1) Nil nitrogen applied
- 2) 40 kg N/ha first node (GS31)
- 3) 80 kg N/ha GS31
- 4) 80 kg N/ha IBS
- 5) 80 kg N/ha Entec urea at GS31
- 6) Greenseeker® GS31 25 kg N/ha ex-lentil  
51 kg N/ha to ex-canola

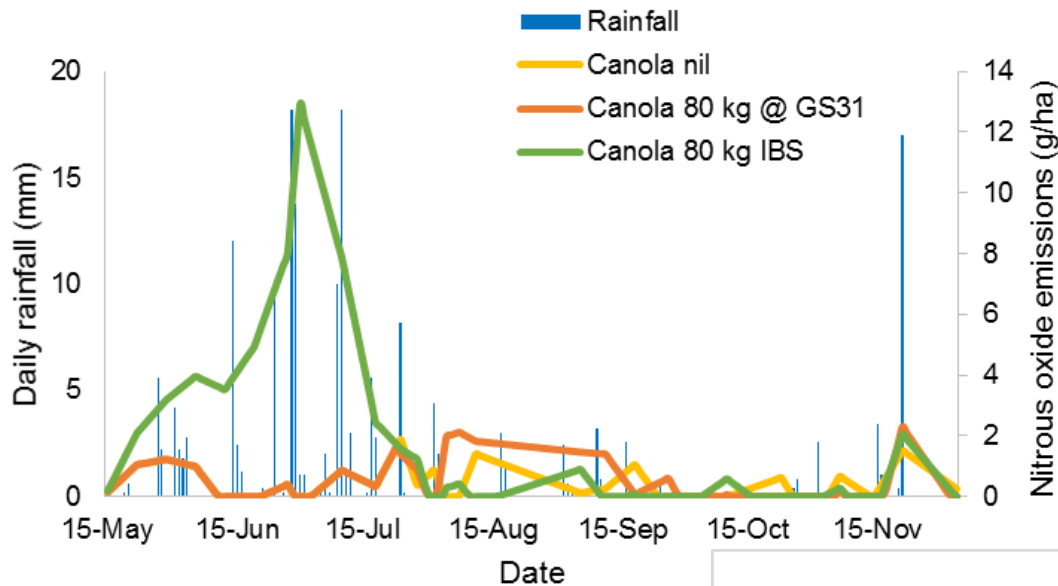

Available soil N at start of season  
10 kg N/ha more under the lentil block

# Wheat grain yield and quality

Previous crop	Nitrogen rate	Grain yield t/ha
Lentils	Nil	3.77
	40 kg @ GS31	4.73
	80 kg @ GS31	6.07
	80 kg @ sowing	5.49
	80 kg @ GS31 + inhibitor	6.04
	25 kg @ GS31	5.54
LSD (P≤0.05)		0.74
Canola	Nil	2.77
	40 kg @ GS31	4.12
	80 kg @ GS31	5.14
	80 kg @ sowing	4.39
	80 kg @ GS31 + inhibitor	5.01
	51 @ GS31	4.33
LSD (P≤0.05)		0.81

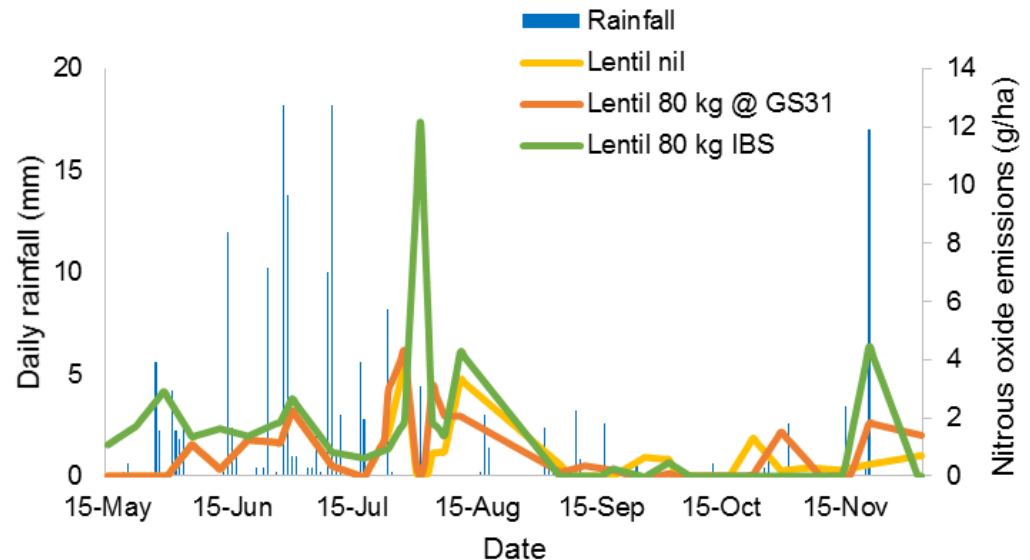

- Wheat yield after lentils were higher compared to wheat after canola.
- 80 kg applied IBS or at GS31 yielded similar, as did the N inhibitor.
- Greater variation in canola and protein was not maintained when N applied IBS.
- Small differences in screenings across N rates.

# Nitrogen lost as nitrous oxide

- IBS 80 kg N/ha > applied at GS31.
- Dependent on rainfall, soil moisture and temperature.
- Higher emissions canola/wheat than lentil/wheat.

- Only 0.4 kg of N<sub>2</sub>O per hectare (8-12 kg N/ha).
- Riverine Plains similar trends, but 4.5× higher N<sub>2</sub>O emissions compared to Hart in half the time.

# Harvest weed seed control – Narrow windrow burning in canola

## Why do the trial?

- Non-chemical weed control strategies.
- Weed seed kill levels of 99% for both annual ryegrass and wild radish have been recorded from the narrow windrow burning of wheat, canola, and lupin chaff and straw.
- The simplicity and low cost of this narrow-windrow system has resulted in its adoption by an estimated 70% of crop producers in WA.
- In South Australia the adoption of this practise is not as high as there have been a limited number of trials able to show the reduction in weed seed number.

# Sampling canola paddocks for annual ryegrass

## Narrow windrow burning – annual ryegrass control

- Narrow windrow burning appears to be an effective tactic for late seed set control for annual ryegrass, provided the seeds can be captured.
- Consider the growth habit of annual ryegrass.
- Option for where grass selective herbicides have failed due to resistance.

Paddock	Stubble/cutting height (cm)	Stubble biomass (t/ha)	
1	42.8	2.8	3
2	31.6	2.4	
3	34.0	2.6	
1	540 (236)	8210 (1357)	93
2	88 (18)	8563 (789)	99
3	52 (15)	10600 (979)	99
